

Worlds: A distributed MMO (*DRAFT*)

Ryan Walker
ryan.cjw@gmail.com

Abstract. A protocol defining how anyone can contribute to an unbounded universe could allow the flexibility to organically grow an MMO faster than any proprietary system. This paper overviews a protocol that enables developers to bolt their game into in common universe.

1 Worlds

1.1 Introduction

For an open software ecosystem to grow organically there should be outlets for contribution. In the context of a massively multiplayer online game the outlets become more complicated then a simple code repository. Fair game mechanics are built on a fragile ecosystem that have negative consequences if managed improperly. The fairness and security of a game are dependent on it's network forming consensus. This is trivially done with conventional methods. A server maintains a secure connection with a player who pipes actions to the server. The server then provides ground truth for the network. Distributed systems require a very different approach. Blockchains present clear deficiencies, they are too slow and the chain would get too large. An alternate method will now be presented.

1.2 Overview

A world, defined as w_k , is a node that designs a user experience and hosts players. Worlds provide the game client which the players interact with. In addition they host servers that form consensus among their world. A world can have up to four adjacent worlds determined by itself. This forms a network, which allows players to explore and share common items(5), experience(7) and currency(4) between worlds.

The worlds engine is an application that manages all things relating to the player.

2 Transport

Players, defined as P_k , can enter a world one of three ways. The first being a **player genesis**(2.3). The second being a **world transfer** (2.2) and the third: a **refuge packages**(2.4). It is possible for players to transfer between adjacent worlds and keep their items and stats. This is done using the mechanics discussed below.

2.1 Transport Hash

A transport hash is a hash of an action ledger, $h_s(AL(P_k, w_k))$, these are secured by the worlds and are used to prove a player is presenting an honest action ledger. The transport hash is formed when a player leaves the world. A **Forward Transport Hash** is a transport hash kept in a special location. This is explained more in the world transfer section, it is defined as $h_{sf}(AL(P_k, w_k))$.

2.2 World Transfer

A detailed state machine outlines how players can move about neighboring worlds. Honest worlds must follow this procedure, if they misbehave they could be risking a **World Disconnect** (3.2) from their neighboring worlds.

Eg: A player, defined as P_1 , wants to move from w_1 to w_2 and then to w_3 (Figure 1), The network values in this scenario are defined as...

Fig. 1. P_1 moving from w_1 to w_2

$$w_1 \xrightarrow{P_1} w_2 \text{ --- } w_3$$

	w_1	w_2	w_3
$h_s(AL(P_1, w_k))$	NULL	NULL	NULL
$h_{sf}(AL(P_1, w_k))$	NULL	NULL	NULL
Neighbor	w_2	$w_1 \ \& \ w_3$	w_2

1. P_1 sends a signed world entry packet to w_2
2. w_2 insures that w_1 is adjasent to itself
3. w_2 must verify that P_1 currently resides in w_1 , this is done by ensuring $h_{sf}(AL(P_1, w_k)) = NULL$. This is found by sending a signed data request to w_1
4. P_1 presents $AL(P_1, w_1)$ to w_2
5. w_1 calculates $h_s(AL(P_1, w_1))$ using the AL on the serverside

6. w_2 calculates $h_s(AL(P_1, w_1))$ using the AL provided by P_1 , the hashes must match
7. (Optional) An **Action Ledger Traceback** (3.1) can be complete
8. P_1 is now granted access to w_2 and can submit actions
9. w_1 must store $h_s(AL(P_1, w_1))$, $AL(P_1, w_1)$ can be deleted

Fig. 2. P_1 in w_2

$$w_1 \text{ ————— } w_2, P_1 \text{ ————— } w_3$$

	w_1	w_2	w_3
$h_s(AL(P_1, w_k))$	$h_s(AL(P_1, w_1))$	<i>NULL</i>	<i>NULL</i>
$h_{sf}(AL(P_1, w_k))$	<i>NULL</i>	<i>NULL</i>	<i>NULL</i>
Neighbor	w_2	$w_1 \ \& \ w_3$	w_2

Fig. 3. P_1 in w_3

$$w_1 \text{ ————— } w_2 \text{ ————— } w_3, P_1$$

	w_1	w_2	w_3
$h_s(AL(P_1, w_k))$	$h_s(AL(P_1, w_1))$	$h_s(AL(P_1, w_2))$	<i>NULL</i>
$h_{sf}(AL(P_1, w_k))$	$h_s(AL(P_1, w_2))$	<i>NULL</i>	<i>NULL</i>
Neighbor	w_2	$w_1 \ \& \ w_3$	w_2

2.3 Player Genesis

Player Genesis is the creation of a new player, for this to occur a player must digitally sign a genesis package with unix time. The world must ensure there are no existing values entered for that player. The player is then instated into the world with all the initial player values set to zero.

2.4 Refugee Package

A refugee package is an action ledger that dates to the time that the package is sent. This allows worlds to reinstate players without the need of a world transfer. This is useful for player that have been orphaned into a world. This typically happens during either a **world disconnect** (3.2) or **world outage** (9.3). This has the effect of splitting the player's history into two forks, which opens the possibility of an **action ledger conflicts** (9.4).

3 Experience

Stuff here

4 Items

Items are defined and generated by worlds. They have transferability to other other worlds only if the two worlds have reached an agreement on their exchangeability.

4.1 Item Listing

An items listing is a data construct that lives at beginning of the item ledger (5.2) for the item. Figure 6 shows an example of a possible item listing. The values are defined in figure 5.

Fig. 4. Item Listing Definitions

ItemID: See Equation 1.
ItemHome: Public key of the world where the item was generated.
Translate: See section ??.
Multiplier: How the ItemClass attributed scale within the worlds
ItemClass: Structure that contains item info

$$ID = h_s(ItemHome || ItemName || ItemClass || ItemClassMembers) \quad (1)$$

Fig. 5. Item Listing

Example of an Itemlisting

```
ItemID: 0xd89ce15212f82fb21b22f983cc6be1a818c73e66a559952bf3d81781
Translate: NULL
ItemHome: 0x52fff7aaae823a5b5af4fb4b30f6da0929f8f05a0a4b0ff629bc25bf
Multiplier: 0.3
ItemName: 'Crossbow'
ItemClass: 'Weapon'
Attack: 5
Defense: 0
TwoHanded: 1
```

4.2 Item Ledger

As described in section 3.5 an item ledger contains the history. Using an item ledger it is possible to trace the item back to it's origin, this can combat the issue with item duplication outlined in section 8. In addition it's also possible to use this to understand how many items worlds are producing, which can be used to prove worlds are not obeying economic caps.

- Header (Signed by World)
 - ItemID (See item listing)
 - UNIX time
 - WorldPublicKey (Issuer of item)
 - PlayerPublicKey (First player to get the item)
- Single Transaction Example
 - Hashed/Signed IL P1
 - Hashed/Signed IL P2
 - Hashed/Signed IL Wx

5 Currency

A common currency between worlds is required. For the game theoretical elements to work this currency must be zero sum, meaning worlds cannot generate it. Ideally it is tracked through an existing blockchain. Implementing it should be as simple as building it into the Worlds engine. Worlds can introduce mechanics for generating revenue, like entrance fees, subscriptions or exchangeability for items. No native currency has been selected at this time.

5.1 Tokens

Worlds may require a currency of their own, this offers the ability to distribute and print tokens. These tokens have exchangeability for the currency described above. Worlds are incentivised to not abuse the system to have decent exchange rates. These tokens should also be tracked on a Blockchain. It is possible that some worlds might acknowledge other worlds currency and offer rewards in game for them.

6 Engine Mechanics

The mechanics below are simply suggestions. As the engine is completely open, worlds are free to impose whatever mechanics they wish. Worlds with drastically different game mechanics will probably not be bordering, this limits gameplay but maintains fairness. Players are able to play in whatever worlds they wish - but they must start from scratch in non-adjacent clusters.

6.1 Action Ledger traceback

The system is not entirely trustless, the neighboring worlds need to trust each other. It is possible for neighboring worlds to have disagreements and still function. For instance, w_1 might introduce an item that w_2 considers too powerful. In a case like this w_1 world can just neglect it. Actions presented using that item would be considered illegal and not entered into the action ledger of the w_1 . Worlds that are not entirely trusted can be audited, consider Figure 4

Fig. 6. Three adjacent worlds

It is possible that w_1 might have conflicts with the rules of w_3 , however w_1 did not choose to be adjacent to w_2 . During the worlds transfer, w_1 would not get the action ledger from w_3 . Completely illegal action could have been committed in w_3 (eg. free money). In this case w_1 can request an **Action Ledger Traceback**(3.1). If this is requested, the player must provide a list of action ledgers that date back to either the player genesis or to the last entry of the world committing the audit. The world then needs to obtain $h_s AL(P_k, w_{k:n})$ from w_k to w_n . If the hashes match then the players history has been confirmed.

Below are some mechanics that can be employed to combat illegal actions.

6.2 World Disconnects

It is possible a world may issue a disconnect of an adjacent world, this means that players may no longer travel between these worlds. This is considered to be the more drastic and can leave players orphaned in the disconnected world, see **Orphaned Players** (??).

6.3 One Way Gates

Worlds can only control their adjacent neighbors, they have no way of controlling the neighbors of their neighbors. Consider Figure 4 If w_1 issues a one-way-gate against w_3 player are no longer allowed to travel back into w_1 if they have traveled through w_3 .

6.4 World Economic Caps

It's possible that worlds may require neighboring worlds to employ a *world economic cap*. This sets a hard cap to the amount of resources that can be distributed to players from the environment in a given time period. This can cap experience points, coins, items, etc...

6.5 Item Ledger

Worlds with greater security requirements might require an item ledger upon world transfers. An item ledger is a data construct that holds an item's history. The first entry should be the item's genesis, which is signed by the world that is issuing the item. To own an item, a player must own the most recent item ledger and for the hash to be verified by the world the player currently resides. For more details see section 5.2.

7 Actions

7.1 Action Ledger

An action ledger, defined as $AL(P_k, w_k)$, is a chronological list of all the signed actions and reactions that has happened to a player in a world. In order to commit an action a player must concatenate a nuance with the action, then sign and send to the world. If the action is legal, it is entered into the world's action ledger for that player. If reactions are to occur to a player, the world must follow the same process and send the signed payload to the players. Players are required to keep their actions ledger dating back to their genesis, worlds are only required to keep **transport hashes** (2.1).

7.2 Action Listing

An *action listing* is a data construct containing possible player actions. It's possible for a world to make their own action listing, defining an unlimited amount of possible player actions. World reactions also reside on this list and start at address code: $0x7F$. There are three types of actions. **Legal Actions** are actions that a world will accept into a player's action ledger if presented, they reside in the world's action listing. **Acceptable Actions** are actions that are to be performed in other worlds only, results from these actions are respected. **Illegal Actions** are actions that a world does not consider to be fair. Illegal actions will simply not show up on a world's action listing. Action ledger tracebacks (3.1) can deal with the occurrence of illegal actions on player's action ledgers.

7.3 Action Listing Translation

Worlds might not share the exact same action listing. An action listing translation is a data construct used to translate actions from one world's action listing to another world's action listing.

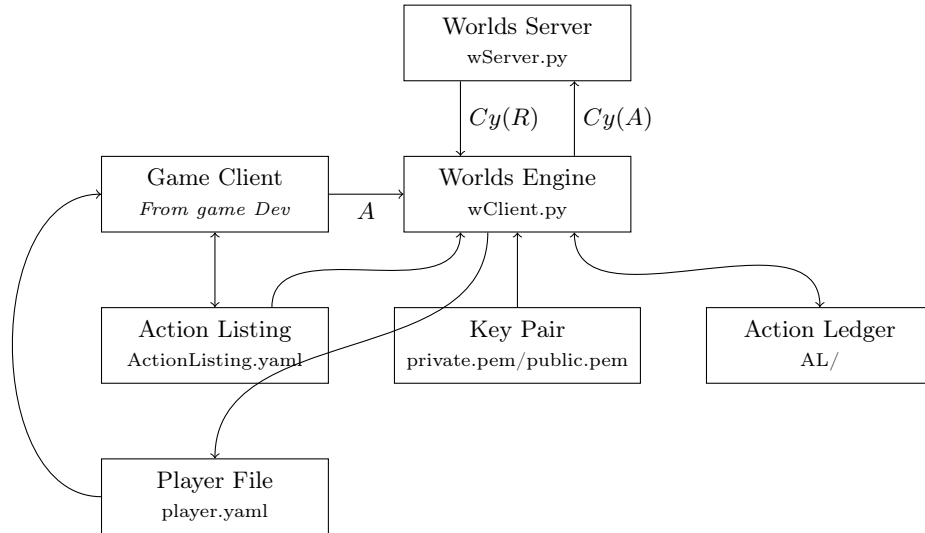

8 System Architecture

A : Action
 $Cy(A)$: Signed Action
 R : Response
 $Cy(R)$: Signed Response

Fig. 7. Section of an Action Listing

```
# toolkit/ActionListing.yaml

# Actions
## Movement commands
Move:
  Code: 0x00
  N: 0x00 # Move North
  E: 0x01 # Move East
  S: 0x02 # Move South
  W: 0x03 # Move West
  Up: 0x04 # Move Up
  Down: 0x05 # Move Down
```

9 Outstanding Issues

9.1 Action Ledger Fragmentation

Action ledger fragmentation is when a significant portion of a players action ledger has become 'neglected' due to worlds with action disagreements. This should be scarce, as worlds with disagreements should consider a disconnect or changing rules.

9.2 Malicious Worlds

Traditionally players would have no recourse against malicious worlds. But it is possible that after a world disconnect adjacent worlds might allow players to rejoin, in addition they have the option to neglect the malicious activity.

9.3 World Outages

In the event of a server outage players may become stranded. The first line of defense for this should be server mirrors, these do not have to be as capable as the main servers but should allow players to exit. In the event of a permanent world outage, adjacent worlds should accept signed **refugee packages**(2.4).

9.4 Action Ledger Conflicts

Figure 8 depicts a possible scenario in which w_2 disconnects from w_3 and w_5 . If a player resides in $w_{3:5}$ there is now no way to return to $w_{1:2}$. $w_{1:2}$ may accept a refugee package and reinstate the player. The player now has the option to play on either forks. In the event of a future path creation between $w_{3:5}$ and $w_{1:2}$ it is possible that that player forks might collide.

Fig. 8. Action Ledger Conflict

This is called an action ledger conflict. Even with an action ledger traceback being done it is possible for items or funds to be duplicated. To mitigate situations like this it should be common practice to avoid joining worlds that have player history that collides. Another possible combatant is **item ledgers** (5.2) and **exchanges rates** (??).
